

Securetore

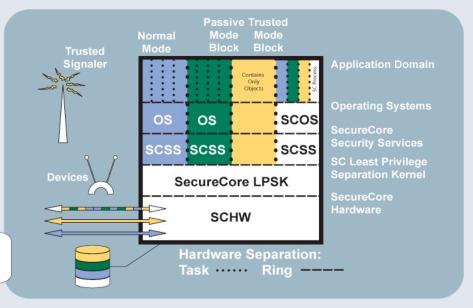

Trustworthy Commodity Computation and Communication

Perform research into design of secure integrated core architectures for trustworthy operation of mobile computing devices.

Including:

Security-aware SecureCore Hardware, SecureCore Least Privilege Separation Kernel, SecureCore Security Services, and secure communications

For use in resource-constrained, ubiquitous computing platforms, i.e. secure embedded systems and mobile computing devices

Comparison to state-of-the-art

Current approach

- · ad hoc revocation mechanisms
- · temporal policies lack low level support
- VMs provide no sharing
- · trusted subjects all or nothing
- · isolated design of layers
- · security with coprocessor

New Approach to

- · revocation
- · temporal access control
- · read down from VM
- · modeling & assured control of trusted subjects
- · codesign of HW/Kernel/Services
- · unified processor

Technical Summary

Anticipated technical advances

- Kernel-based fine grain control of trusted subjects
 - A trusted subject may only access certain objects in its trust range minimizes reliance on the correctness of application-domain security services
- Formal model and architectural solution define "controlled interference" for trusted subjects.
- Subjects can "read down" to blocks at lower levels, as allowed by kernel
 - Also, kernel-controlled controlled write-up ("blind"write)
 Traditional separation kernel architectures lack these abilities
- Exportation of hardware interrupts to the client OS
 - $\circ \qquad \text{Enables OS-specific interrupt handling regarding subjects' access violations to individual resources}$
 - Traditional separation kernel architectures only provide block-level notification
- Kernel-based "intransitive information flow" enforcement
- Traditionally requires trusted subjects
- SecureCore supports, for example, a policy whereby each subject may only read down one level, because of data integrity or system assurance concerns.

Innovation

Utilization of hardware/kernel/SCSS co-design to construct SCSS interface such that Secure Core unique security features do not require modifications to the client OS.

Recent Developments

- Hardware and software architecture and authorization model to support temporal access controls
- Hardware and software mechanisms to support object reuse requirements
 - Re-examination and synthesis of security principles relative to current technology trends and target platform
